1. The exam has 4 questions with a total of 100 points. You have 80 minutes to take the exam. Questions have different numbers of points so please allocate your time to each question accordingly.

2. Please write the answer in the designated area underneath each question. If you need more room for your answer, please indicate as such, and continue your response on the blank page at the end of all questions. No additional pages will be allowed.

3. Scratch paper will be provided and collected at the end of the exam, but will not be graded.

4. All answers should be justified, unless otherwise stated.

5. The exam is closed book but you are allowed one double-sided sheet of notes. A list of variables and reference information on the mining algorithm and the hash function are provided at the end of the exam. No other materials are allowed.

Good luck!

Name: 

SUID: 

1. (24 points) True-false questions (no explanations required). 2 points for a correct answer, 0 points for an incorrect answer. 1 point for leaving the answer blank. Knowing you don’t know something has value.

Please shade your answer in completely to receive full credit.

</table>
Reasons:

(a) A block containing a transaction which is conflicting with respect to a predecessor block’s UTXO state is invalid.
(b) Successful queries are probabilistic, so they may sometimes be closer than $\Delta$ apart.
(c) The target can be made easier as $\Delta$ decreases.
(d) Honest miners choose the nonce as a random $\kappa$-bit string.
(e) Self-explanatory.
(f) It will fail because the proof-of-work equation will not be satisfied (coinbase transaction does not have a signature).
(g) The adversary’s mining rate is also limited by her hashing power because valid blocks must satisfy the proof-of-work equation.
(h) The adversary cannot generate signatures because that would require the honest party’s secret key.
(i) A censorship attack may violate liveness but not safety.
(j) Since there is only one honest miner, there can’t be any forks.
(k) A valid block can have only one parent block.
2. (16 points) Let $H : \{0,1\}^* \rightarrow \{0,1\}^\kappa$ be a collision-resistant hash function and define $G : \{0,1\}^* \rightarrow \{0,1\}^{2\kappa}$ as $G(x) = H(x) \parallel H(x)$. Show that $G$ is a collision-resistant hash function.

Solution:

We will prove this by contradiction. Suppose that $G$ is not collision-resistant. Then there exists a PPT adversary $A$ such that $\Pr[\text{collision} \; G, \; A(\kappa) = 1 \} = \text{non-negl}(\kappa)$. We will create a PPT adversary $A'$ that breaks the collision-resistance of $H$.

On input $1^\kappa$ the adversary $A'$ works as follows. She invokes $A$ with input $1^\kappa$ to retrieve $x_1, x_2$. She then returns $x_1, x_2$. If $A$ is successful, then $G(x_1) = G(x_2)$ and $x_1 \neq x_2$.

This means that $H(x_1) \parallel H(x_1) = H(x_2) \parallel H(x_2)$, and therefore $H(x_1) = H(x_2)$ and $A'$ is successful. Therefore,

$$\Pr[\text{collision} \; H, \; A'(\kappa) = 1\} = \Pr[\text{collision} \; G, \; A(\kappa) = 1\}$$

Since $\Pr[\text{collision} \; G, \; A(\kappa) = 1\}$ is non-negligible in $\kappa$, then $\Pr[\text{collision} \; H, \; A'(\kappa) = 1\}$ is also non-negligible in $\kappa$. This contradicts the assumption that $H$ is collision resistant.

\begin{algorithm}[h]
\begin{algorithmic}[1]
\Function{$A'$}{$1^\kappa$}
\State $x_1, x_2 \leftarrow A$
\State \Return $x_1, x_2$
\EndFunction
\end{algorithmic}
\end{algorithm}
3. (30 points) We are working in a UTXO longest chain system with a block reward of 50 units and a confirmation rule of $k = 6$. Consider the transaction graph illustrated in Figure 1.

![Transaction Graph](image)

Figure 1: The transaction graph.

The party $Q$ has adopted a chain $C_Q$ such that $L_Q = (\text{tx}_0, \text{tx}_1, \text{tx}_2)$, while the transactions recorded in $C_Q$ are $(\text{tx}_0, \text{tx}_1, \text{tx}_2, \text{tx}_3, \text{tx}_4)$. The party $Q$ is a miner who collects transactions into a mempool to create a template block to mine on.

(a) (6 points) In what order should the rest of the transactions ($\text{tx}_5$ through $\text{tx}_{10}$) be arranged into a block by $Q$ so that $Q$'s coinbase proceeds are maximized?  

Solution: $\text{tx}_6, \text{tx}_7, \text{tx}_{10}$ or $\text{tx}_6, \text{tx}_{10}$.

Possible valid block configurations:

i. $\text{tx}_5, \text{tx}_9$ with the total fee of 3 units

ii. $\text{tx}_6, \text{tx}_7, \text{tx}_{10}$ with the total fee of 6 units

Thus, to maximize coinbase proceeds miner should chose $\text{tx}_6, \text{tx}_7, \text{tx}_{10}$. Transaction $\text{tx}_7$ does not have any fee, so excluding it from the block does not change the coinbase proceeds.
(b) (6 points) What is the output value in Q’s new coinbase transaction?

Solution: 56 units: 50 units of the block reward and 6 units of the fees.

(c) (4 points) If Q successfully mined a block in part (a) and the block is buried under \( k = 6 \) other blocks, what does the new ledger \( \mathbb{L}_Q \) report?

Solution: \( \mathbb{L}_Q = (tx_0, tx_1, tx_2, tx_3, tx_4, tx_6, tx_7, tx_{10}) \)

(d) (6 points) Which transactions (among \( tx_5 \) through \( tx_{10} \)) are missing from Q’s ledger and why?

Solution: \( tx_5, tx_8, tx_9 \)

i. \( tx_5 \) and \( tx_6 \) are double-spending transactions, so if \( tx_6 \) is in the ledger, \( tx_5 \) cannot be included

ii. \( tx_8 \) fails the law of conservation, output of 30 units is larger than input 20 units

iii. \( tx_9 \) spends the output of \( tx_5 \), which is not in the ledger
(e) (4 points) How much unspent money does Q have in the system, if we also include his mining proceeds?

**Solution:** The transaction tx9 is not in the ledger, thus, Q only has 56 units of his mining proceeds.

(f) (4 points) How much money do the parties A, B, and P have, provided they are not mining any blocks?

**Solution:**

i. A has 21 units: 10 units from tx2, 10 units from tx4 and 1 unit from tx7

ii. B has 2 units: 1 unit from tx6 and 1 unit from tx7

iii. P has 1 unit from tx10
4. (30 points) Consider the sequence of successful honest party queries in Figure 2. Recall that a successful query satisfies the proof-of-work equation $H(B) \leq T$.

![Figure 2: A sequence of honest successful query events.](image)

Consider executions\(^1\) with maximum network delay $\Delta = 1$. You are a powerful rushing adversary and you have 7 successful queries at your disposal. You are given the (fictitious) ability to place your successful queries at whichever points on the timeline you prefer. Honest parties gossip blocks, but you can schedule the delay of each honest message freely, as long as it is within a maximum of $\Delta$. As the adversary, you are also allowed to choose how each honest party will choose to break ties among competing chains of the same length.

Describe the following executions, consistent with the above timeline. For each of the below executions, draw the block tree. For each block in the block tree, indicate whether it was honestly or adversarially mined, and what time it was mined at. You can use just the integer part of the time (for example, you can write "1" for a block that was mined at time "1.4"). Your three executions do not all have to be different.

(a) (10 points) An execution in which Common Prefix with $k = 7$ is violated. What is the adopted chain tip of each honest party in your execution?

Solution:

![Figure 3: One of executions violating Common Prefix with $k = 7$](image)

\(^1\)An execution is the transcript of everything that happened, including who mined each block, when each block was mined, what the whole private and public blocktree looks like, when and if each block was broadcast, and when it was received, including all adversarial actions.
(b) (10 points) An execution in which three different honest parties adopt chains $C_1$, $C_2$ and $C_3$ such that $C_1[: -k], C_2[: -k], C_3[: -k]$ are different from each other for $k = 4$. ($C[: -k]$ means the chain resulting from removing the last $k$ blocks in a chain $C$.)

Solution:

![Figure 4: One of the executions violating Common Prefix with $k = 4$](image)

Figure 4: One of the executions violating Common Prefix with $k = 4$

(c) (10 points) An execution **minimizing** Chain Quality (across all executions) of the whole chain for some honest party. What is the Chain Quality of the chain adopted by your chosen honest party?

Solution: $CQ = \frac{2}{9}$

![Figure 5: One of the executions minimizing Chain Quality.](image)

Reference

Some helpful definitions are provided below.

Definition 1 (Collision Resistance). A hash function $H : \{0, 1\}^* \rightarrow \{0, 1\}^\kappa$ is collision resistant if for all PPT adversaries $A$,

$$
\Pr[collision-game_{H,A(\kappa)} = 1] = \text{negl}(\kappa).
$$

The game is defined in Algorithm 2.

Algorithm 2 The collision-finding game for a hash function $H$.

```
1: function COLLISION-GAME$H,A(\kappa)$
2: $x_1, x_2 \leftarrow A(1^\kappa)$
3: return $H_\kappa(x_1) = H_\kappa(x_2) \land x_1 \neq x_2$
4: end function
```

Definition 2 (Weak Conservation Law). A transaction $tx$ satisfies the Weak Conservation Law if

$$
\sum_{i \in \text{tx.ins}} i.v \geq \sum_{o \in \text{tx.outs}} o.v.
$$

Definition 3 (Velocity). The velocity $\tau$ of a chain of an honest party $P$ between times $r_1 < r_2$ is the ratio $\frac{|C_P^{r_2} - C_P^{r_1}|}{r_2 - r_1}$.

Definition 4 (Common Prefix). The Common Prefix virtue, parametrized by $k \in \mathbb{N}$, is satisfied if for all honest parties $P_1, P_2$ and for all times $r_1 \leq r_2$, it holds that $C_{r_1}^{P_1}[-k] \preceq C_{r_2}^{P_2}$.

Definition 5 (Chain Quality). The Chain Quality of a chain chunk $C$ is defined as the ratio of the honestly produced blocks divided by the total blocks within that chain chunk.

Our variables.

- $\kappa$: The security parameter
- $A$: The uniform PPT adversary
- $\Pi$: The honest protocol
- $H$: The hash function
- $G$: The genesis block, an honestly mined reference block
- $\Delta$: The maximum network delay
- $T$: The mining target
- \( p \): The probability of a successful query
- \( n \): The total number of parties (includes both honest and adversarial)
- \( t \): The number of adversarial parties
- \( q \): The hashing power of a single party per unit of time
- \( k \): The Common Prefix parameter, in blocks
- \( \mu \): The Chain Quality parameter, as a proportion
- \( \tau \): The velocity, in blocks per unit of time

**Terminology.**

- The proof-of-work equation: \( H(B) \leq T \).
- A *successful query* is a fresh query to the random oracle \( H \) that satisfies the proof-of-work equation.
- A *convergence opportunity* is an honest successful query which is spaced at least \( \Delta \) apart from all other honest successful queries.
- A *negligible function* is eventually smaller than all inverse polynomials.
- A block tree has the *Common Prefix* virtue with parameter \( k \) if, for any two chains \( C_1, C_2 \) currently adopted by honest parties, \( C_1[-k] \) is a prefix of \( C_2 \).

**Algorithms.**

**Algorithm 3** The mining algorithm.

```plaintext
1: function Mine(s, \( \overline{x} \))
2:   \( \text{ctr} \leftarrow \{0, 1\}^k \)
3:   while true do
4:     \( B \leftarrow s \parallel \overline{x} \parallel \text{ctr} \)
5:     if \( H(B) \leq T \) then
6:       return \( B \)
7:     end if
8:     \( \text{ctr} \leftarrow \text{ctr} + 1 \)
9:   end while
10: end function
```

**Chain addressing notation.**

- \( |\mathcal{C}| \): Chain length
- \( \mathcal{C}[i] \): \( i \)th block in the chain (0-based). The block height is \( i \).
- \( \mathcal{C}[-i] \): \( i \)th block from the end.
• $C[0]$: Genesis (by convention honest).
• $C[-1]$: The tip.
• $C[i:j]$: Chain chunk from block $i$ (inclusive) to $j$ (exclusive).
• $C[:j]$: Chain chunk from the beginning and up to block $j$ (exclusive).
• $C[i:]$: Chain chunk from block $i$ (inclusive) onwards.
• $C[:k]$: The stable chain.
